Data Structure and Algorithm

Laboratory Activity No. 7

Doubly Linked Lists

Submitted by:
Gabijan, Rhovic M.

Instructor:
Engr. Maria Rizette H. Sayo

August 23, 2025

I. Objectives

Introduction

A doubly linked list is a type of linked list data structure where each node contains three components:

Data - The actual value stored in the node
Previous pointer - A reference to the previous node in the sequence
Next pointer - A reference to the next node in the sequence.

This laboratory activity aims to implement the principles and techniques in:

- Writing algorithms using Linked list
- Writing a python program that will perform the common operations in a Doubly linked list
- A doubly linked list is particularly useful when you need frequent bidirectional traversal or easy deletion of nodes from both ends of the list.

II. Methods

- Using Google Colab, type the source codes below:

```
class Node:
    """Node class for doubly linked list"""
    def __init__(self, data):
        self.data = data
        self.prev = None
        self.next = None

class DoublyLinkedList:
    """Doubly Linked List implementation"""

    def __init__(self):
        self.head = None
        self.tail = None
        self.size = 0

    def is_empty(self):
        """Check if the list is empty"""
        return self.head is None

    def get_size(self):
        """Get the size of the list"""
```

```
    return self.size

def display_forward(self):
    """Display the list from head to tail"""
    if self.is_empty():
        print("List is empty")
        return

    current = self.head
    print("Forward: ", end="")
    while current:
        print(current.data, end="")
        if current.next:
            print(" ↔ ", end="")
        current = current.next
    print()

def display_backward(self):
    """Display the list from tail to head"""
    if self.is_empty():
        print("List is empty")
        return

    current = self.tail
    print("Backward: ", end="")
    while current:
        print(current.data, end="")
        if current.prev:
            print(" ↔ ", end="")
        current = current.prev
    print()

def insert_at_beginning(self, data):
    """Insert a new node at the beginning"""
    new_node = Node(data)

    if self.is_empty():
        self.head = self.tail = new_node
```

```
        else:
            new_node.next = self.head
            self.head.prev = new_node
            self.head = new_node

        self.size += 1
        print(f"Inserted {data} at beginning")

    def insert_at_end(self, data):

Answer the following questions:

1. What are the three main components of a Node in the doubly linked list implementation, and what does the __init__ method of the DoublyLinkedList class initialize?

- The main components of a Node in the doubly linked list are Data which stores the actual information, prev which is a node before the current one, and Next which is a node after the current one. In addition, __init__ method in DoublyLinkedList class initialize an empty list;

```
head = None
tail = None
size = 0
```

2. What are the three main components of a Node in the doubly linked list implementation, and what does the __init__ method of the DoublyLinkedList class initialize?

```
def insert_at_beginning(self, data):
    new_node = Node(data)

    if self.is_empty():
        self.head = self.tail = new_node
    else:
        new_node.next = self.head
        self.head.prev = new_node
        self.head = new_node

    self.size += 1
```

- The three components of a Node are data, prev, and next. The __init__ function of the DoublyLinkedList initializes head = None, tail = None, and size = 0. In the code presented in this question, it shows that the user will insert or add a new node at the start of a list.

3. How does the reverse method work? Trace through the reversal process step by step for a list containing [A, B, C], showing the pointer changes at each iteration

```
def reverse(self):
    if self.is_empty() or self.head == self.tail:
        return

    current = self.head
    self.tail = self.head

    while current:
        temp = current.prev
        current.prev = current.next
        current.next = temp
        current = current.prev

    if temp:
        self.head = temp.prev
```

The reverse methods work by swapping the prev and next pointers of every node. Head is “A” and the tail would be “C.” The “B” will be sa prev, “A” will become the tail, an the “C” will become a head, making the list reversed and reads [C,B,A].

III. Results

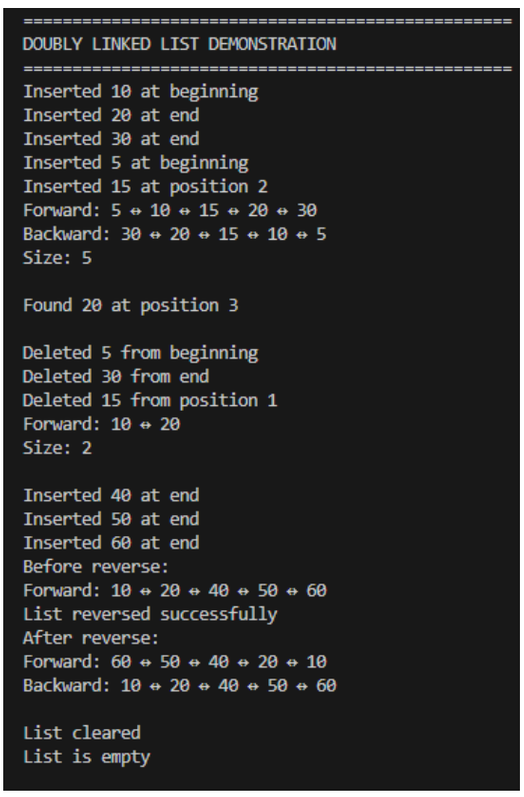

Figure 1.0 Output

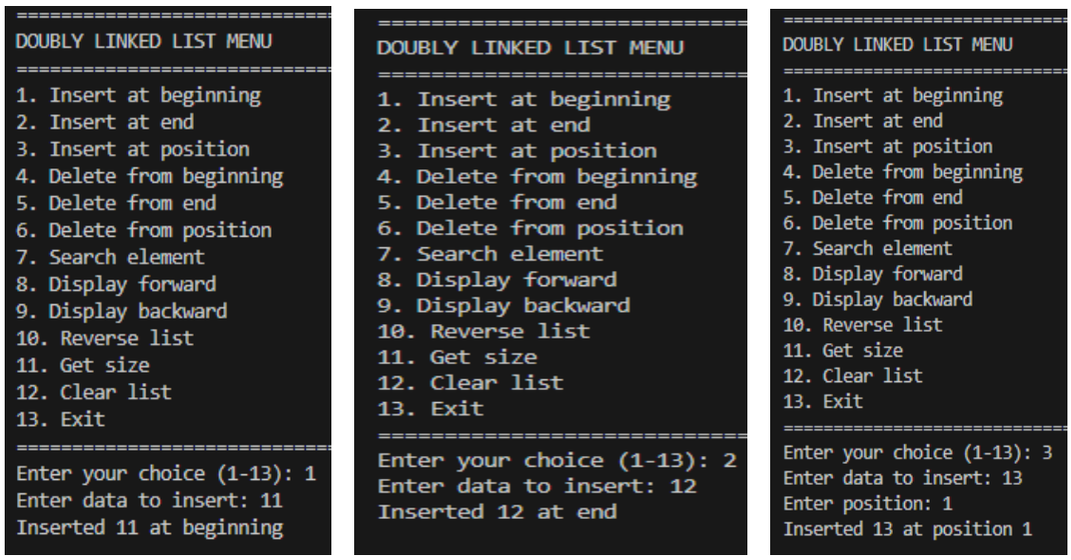

Figure 2.0 Insert at Beginning, End, and Position

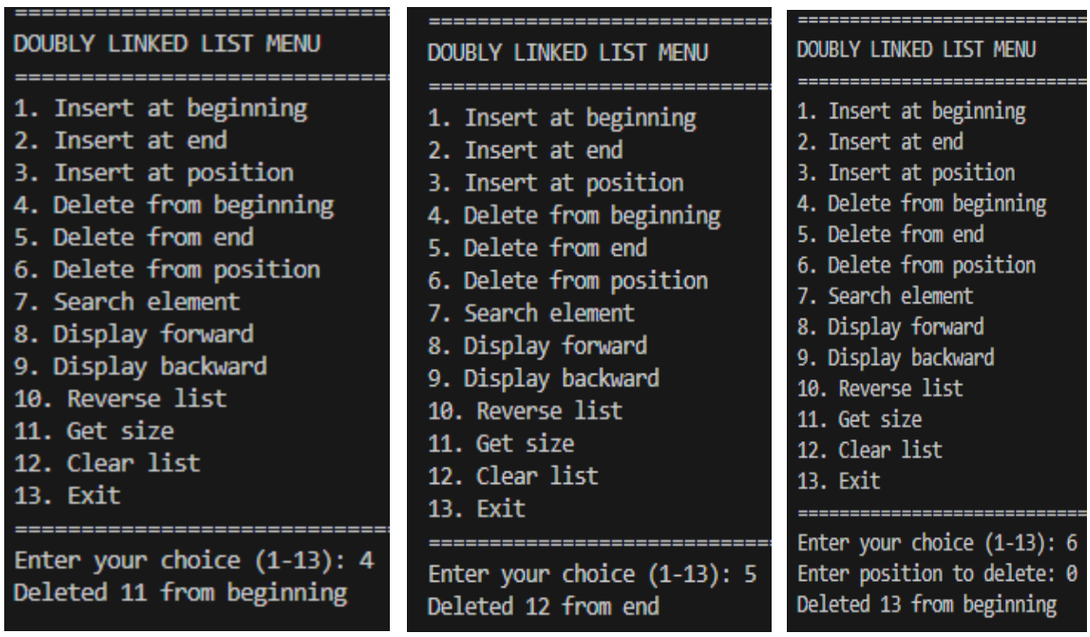

Figure 3.0 Delete at Beginning, End, and Position

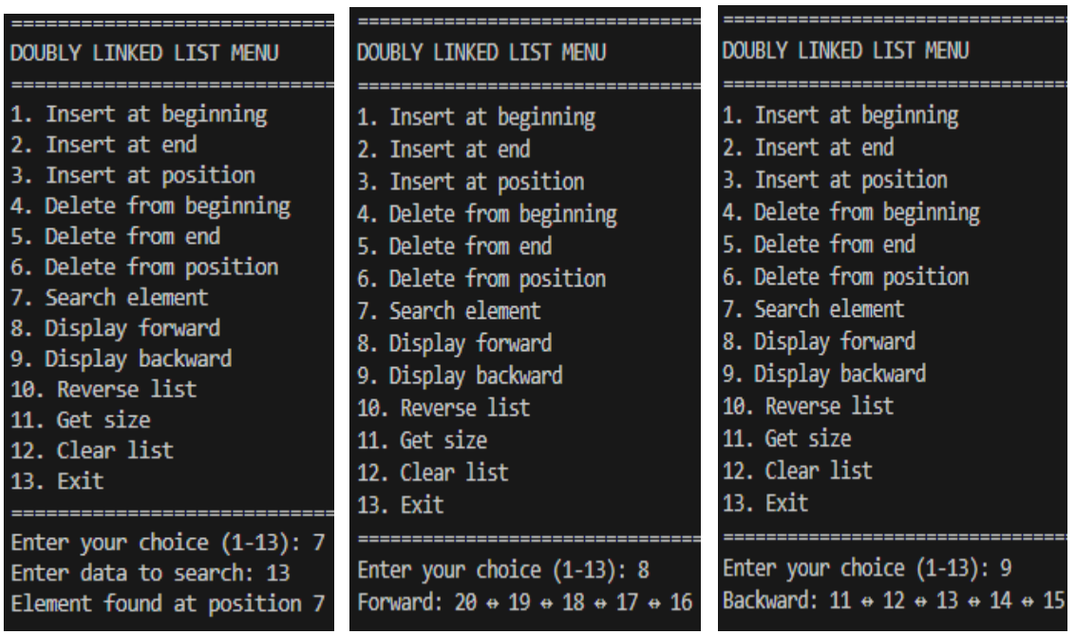

Figure 4.0 Search, Display Forward and Backward

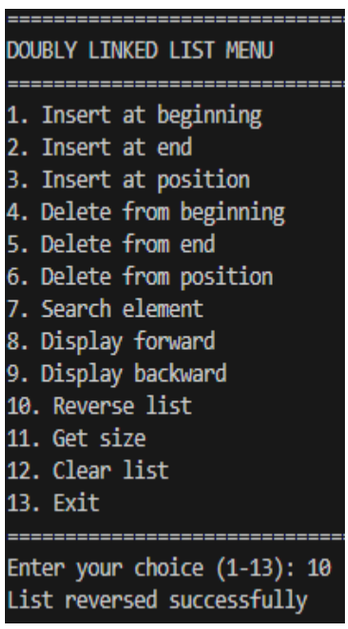

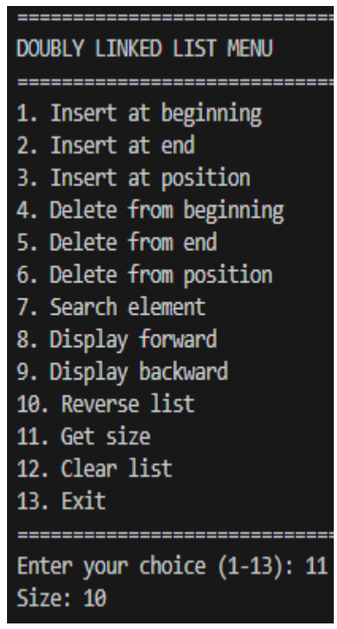

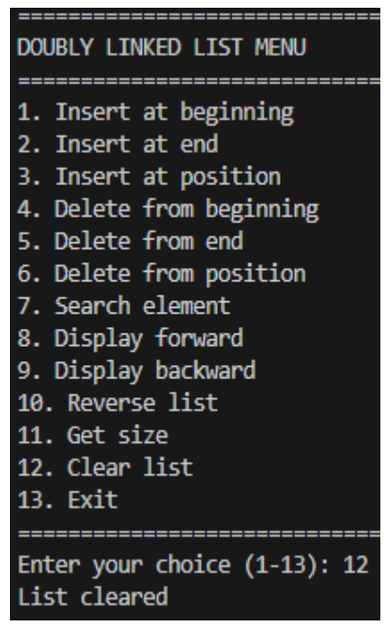

Figure 5.0 Reverse List, Get Size, and Clear

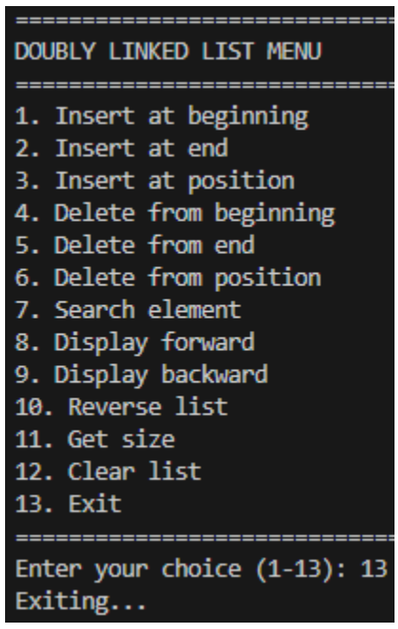

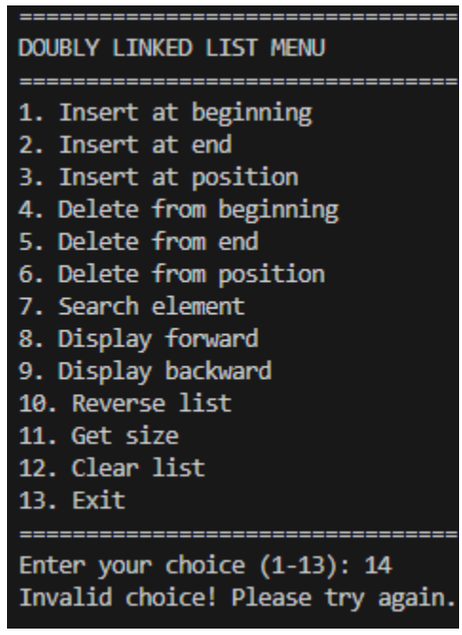

Figure 6.0 Exit and Invalid choice

The program demonstrates the usage of Doubly linked list that stores the data, manipulate its position, insert, clear, get the size of the data, and search the data inserted in the program.

IV. Conclusion

In conclusion, Linked list is a linear data structure, in which element is stored in a chain liked structure that has head and tail. In Doubly Linked List is has prev and next initialize method allowing user to manipulate the position, inserting data at the position, as well as searching the data.
